### SOLUTIONS

#### QUESTION 1

$$x = \ln x$$

(a) 
$$u = \log x$$

$$du = \frac{1}{x} dx$$

 $x=e^2, u=2$ x = e, u = I

$$\int_{-\pi}^{\pi} \frac{1}{u} du$$

$$= \lfloor \log u \rfloor_1^2$$
$$= \log 2 - \log 1$$

$$= \log 2$$

$$(2-x)(x+2)$$

$$\frac{5}{(2-x)(x+2)} - 1 > 0$$

$$\frac{5-(4-x^2)}{(2-x)(x+2)} > 0$$

$$\frac{x^2+1}{(2-x)(x+2)} > 0$$

i.e. 
$$(2-x)(x+2) > 0$$

Test x = 0, true

$$\therefore$$
 Solution is  $-2 < x < 2$ 

(c) Line 
$$PQ$$
 has equation  $\frac{y-y_1}{x-x_1} = \frac{y_2-y_1}{x_2-x_1}$ 

$$\frac{y+3}{x+3} = \frac{5+3}{1+3}$$

$$y + 3 = 2(x + 3)$$
  
 $y = 2x + 3$ 

$$y=2x+3$$

A lies on 
$$PQ$$
 since, when  $x = \frac{1}{2}$ ,  $y = 2(\frac{1}{2}) + 3$ 

$$x_{A} = \frac{mx_{Q} + nx_{P}}{m + n}$$

 $\frac{1}{2} = \frac{m(1) + n(-3)}{m + n}$ 

m+n=2m-6n

m=7n

$$y_{A} = \frac{my_{Q} + ny_{P}}{m + n}$$

 $4 = \frac{m(5) + n(-3)}{n}$ 

$$4m + 4n = 5m - 3n$$

$$m = 7n$$

$$m = 7n$$

$$\frac{m}{n} = 7$$

$$m: n = 7: 1$$

i.e. A divides the line segment 
$$PQ$$
 in the ratio  $7:1$ 

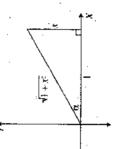

i.e. m : n = 7 : 1

7= <u>m</u> --

#### (d) Let $\tan^{-1} x = \alpha$

$$\therefore \tan \alpha = x \qquad \text{for } -\frac{\pi}{2} < \alpha < \frac{\pi}{2}$$

and  $\alpha$  can be represented as a first quadrant angle.

Then 
$$\cos \alpha = \frac{1}{\sqrt{1+x^2}}$$

so that 
$$\cos^{-1} \frac{1}{\sqrt{1+x^2}} = \alpha$$

$$\therefore \tan^{-1} x = \cos^{-1} \frac{1}{\sqrt{1 + x^2}}$$

(e) Remainder = 
$$P(-4) = -64 + 16 + 2$$

#### QUESTION 2

(a)  $7! \times {}^4C_2$ 

(b) 
$$(1-2x)^6 = \sum_{k=0}^6 {n \choose k} (-2x)^k$$

$$(1-3x+2x^3)(1-2x)^6$$

$$= (1 - 3x + 2x^{3})[1 + {\binom{6}{1}}(-2x) + {\binom{6}{2}}(-2x)^{2} + {\binom{6}{3}}(-2x)^{3} + {\binom{6}{4}}(-2x)^{4} + {\binom{6}{3}}(-2x)^{5} + {\binom{6}{6}}(-2x)^{6}]$$

The x5 terms arise from

$$1 \times {\binom{6}{3}}(-2x)^5 - 3x[\binom{6}{4}(-2x)^4] + \frac{1}{2}x^3[\binom{6}{4}(-2x)^2]$$

$$=-192x^5-720x^5+120x^5$$

$$=-797 r^{5}$$

$$\therefore$$
 Coefficient of  $x^5$  term is  $-792$ 

(c)  $\cos 54^{\circ} \cos \alpha + \sin 54^{\circ} \sin \alpha = \sin 2\alpha$ 

$$cos(54^{\circ} - \alpha) = cos(90^{\circ} - 2\alpha)$$

$$\therefore 54^{\circ} - \alpha = \pm (90^{\circ} - 2\alpha) + 360^{\circ}n$$

$$54^{\circ} - \alpha = 90^{\circ} - 2\alpha + 360^{\circ}n$$
  $| 54^{\circ} - \alpha = -(90^{\circ} - 2\alpha) + 360^{\circ}n$ 

$$\alpha = 36^{n} + 360^{\circ}n$$

 $54^{\circ} - \alpha = -90^{\circ} + 2\alpha + 360^{\circ}n$ 

$$3\alpha = 144^{\circ} - 360^{\circ}n$$
$$\alpha = 48^{\circ} - 120^{\circ}n$$

(d) 
$$\frac{d}{dx} \left[ \frac{\tan^2 x}{x} \right]$$

$$= \frac{2x \tan x \sec^2 x - \tan^2 x}{x^2}$$

(e) 
$$f(x) = 2x^2 + x$$

$$f^{\dagger}(a) = \lim_{h \to 0} \frac{f(a+h) - f(a)}{h}$$

$$= \lim_{h \to 0} \frac{2(a+h)^2 + a + h - (2a^2 + a)}{h}$$

$$= \lim_{h \to 0} \frac{2a^2 + 4ah + 2h^2 + a + h - 2a^2 - a}{h}$$

$$=\lim_{h\to 0}\frac{4ah+2h^2+h}{h}$$

$$= \lim_{h \to 0} 4a + 2h + 1$$

$$= \lim_{h \to 0} 4a + 2h$$
$$= 4a + 1$$

#### QUESTION 3

(a) 
$$y = x^2 - 4x - 1$$

$$y+1=x^2-4x$$

$$x^2 - 4x + 4 = y + 5$$

$$(x-2)^2 = y+5$$

$$(x-2)^2 = 4(\frac{1}{4})(y+5)$$

Focal length = 
$$\frac{1}{4}$$

$$\therefore$$
 Focus is  $(2, -4\frac{3}{4})$ 

Directrix has equation 
$$y = -5\frac{1}{4}$$

(b) With one digit: 6

With two digits:  $^6P_2 = 30$ 

With three digits:  $3 \mid 5 \mid 4 \mid = 60$ 

Total = 96

(c) (i) Let  $\angle BAF = x$ 

$$\therefore \angle FAC = x (AF \text{ bisects } \angle BAC)$$

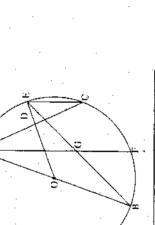

$$\therefore \angle AOD = 2x (DA = DO)$$

$$\therefore \angle ABF = x$$

(angle at centre =  $2 \times \text{angle at circumference}$ )

$$\therefore \angle BAF = \angle ABE = x$$

$$\therefore GA = GB$$

(ii) 
$$\angle AGE = 2x$$
 (Exterior  $\angle$  of  $\triangle GAB$ )

$$\therefore \angle AGE = \angle AOD = 2x$$

 $\therefore AOGE$  is a cyclic quadrilateral (angles subtended by AE proved equal)

(iii) 
$$\angle BEC = \angle BAC$$
 (angles subtended by  $BC$ )

$$\therefore ZBEC = ZAGE = 2x$$

 $\therefore BC || FA$  (alternate  $\angle s$  proved equal)

**QUESTION 4** 

Mathematics Extens: 1 HSC 2004

(a) 
$$\sum_{r=1}^{n} \frac{r^2}{(2r-1)(2r+1)} = \frac{1^2}{1\times 3} + \frac{2^2}{3\times 5} + \dots + \frac{n^2}{(2n-1)(2n+1)}$$

If 
$$n = 1$$
, LHS =  $\frac{1^2}{1 \times 3} = \frac{1}{3}$   
RHS =  $\frac{1(2)}{2(3)} = \frac{1}{3}$ 

 $\therefore$  The statement is true for n=1

Assume that the statement is true for n = k, a positive integer.

i.e. 
$$\frac{1^2}{1\times 3} + \frac{2^2}{3\times 5} + \dots + \frac{k^2}{(2k-1)(2k+1)} = \frac{k(k+1)}{2(2k+1)}$$

So, when n = k + 1

LHS = 
$$\frac{1^2}{1 \times 3} + \frac{2^2}{3 \times 5} + \dots + \frac{k^2}{(2k-1)(2k+1)} + \frac{(k+1)^2}{(2k+1)(2k+3)}$$

$$= \frac{k(k+1)}{2(2k+1)} + \frac{(k+1)^2}{(2k+1)(2k+3)}$$
 by assumption

$$=\frac{k(k+1)(2k+3)+2(k+1)^2}{2(2k+1)(2k+3)}$$
$$=\frac{(k+1)(2k^2+3k+2k+2)}{2(2k+1)(2k+3)}$$

$$\frac{(k+1)(2k^2+5k+2)}{2(2k+1)(2k+3)}$$

$$=\frac{(k+1)(2k+1)(k+2)}{2(2k+1)(2k+3)}$$

$$= \frac{(k+1)(k+2)}{2(2k+3)} = RHS$$

: If the statement is true for n = k, then it is true for n = k + 1.

But it is true for n = 1, and so true for n = 2, and hence by induction it is true for all positive integers.

(b) (i) Let O be the centre of the semi-circle and join OC.

Let O be the centre of the semi-circle and join OC.

$$\angle OCB = \alpha$$
.  $(OC = OB)$ 

.. Area of segment cut off by CB  $= \frac{1}{2}(1)^{2} \left[ \pi - 2\alpha - \sin \left( \pi - 2\alpha \right) \right]$ 

 $=\frac{1}{2}\left(\pi-2\alpha-\sin 2\alpha\right)$ 

(ii) Area of segment =  $\frac{1}{2}$  (area of semi-circle)

 $\frac{1}{2}(\pi - 2\alpha - \sin 2\alpha) = \frac{1}{2}(\frac{1}{2}\pi)$ 

 $\pi - 2\alpha - \sin 2\alpha = \frac{\pi}{2}$ 

 $2\pi - 4\alpha - 2\sin 2\alpha = \pi$ 

 $\therefore$  2 sin 2 $\alpha$  + 4 $\alpha$  =  $\pi$ 

(iii) Let  $f(\alpha) = 2 \sin 2\alpha + 4\alpha - \pi$ 

f(0.4) = -0.106 < 0f(0.5) = +0.541 > 0 Change in sign proves that a root lies between  $\alpha=0.4$  and  $\alpha=0.5$ 

(iv) Taking  $\alpha = 0.45, f(0.45) = 0.225 > 0$ 

But A(0.4) < 0

.: Root lies closer to 0.4 than 0.5

QUESTION 5

(a) (i)  $T = T_O + Ae^{-k}$ 

 $\therefore Ae^{-k} = T - T_0$ 

Now  $T = T_O + Ae^{-k}$ 

 $\frac{dT}{dt} = -kAe^{-kt}$ 

 $-k(7-T_0)$ 

(ii) When t = 0, T = 100

When t = 3, T = .70

 $T = T_O + Ae^{-kt}$ 

 $100 = 25 + Ae^{o}$ 

Now  $T = 25 + 75e^{-kt}$ ∴ A = 75

 $70 = 25 + 75e^{-34}$ 

-3k = ln(0,6)

 $k = \frac{ln0.6}{-3}$ 

(iii)  $T = 25 + 75e^{-0.1704}$ 

T = 50

 $50 = 25 + 75e^{-0.1704}$ 

 $e^{-0.170v} = \frac{25}{75}$ 

 $-0.170t = ln(\frac{1}{2})$ 

 $t = \frac{ln(\frac{1}{3})}{-0.170}$ 

 $t = 6.45 \, \text{min}$ 

## (b) (i) Applying cosine rule to

triangle ABC:

urangse 
$$ABC$$
:  
 $y^2 = x^2 + y^2 - 2xy \cos \alpha$   
 $2xy \cos \alpha = x^2$ 

$$\cos \alpha = \frac{x^2}{2xy}$$

 $=\frac{x}{2y}$ 

(ii) 
$$\angle BAC = \alpha$$
 ( $\triangle ABC$  isosceles)

$$\therefore$$
 Z4CB = 180° -- 2 $\alpha$  (angles of  $\triangle$  ABC)

$$\angle ADC = 90^{\circ}$$
 (angle in a semi-circle)

In 
$$\triangle ADC$$
;  $\cos(180 - 2\alpha) = \frac{DC}{y}$ 

$$-\cos 2\alpha = \frac{DC}{y}$$

$$\therefore DC = -y \cos 2\alpha$$

$$=-y(\frac{2x^2}{4y^2}-1)$$

 $=-y(2\cos^2\alpha-1)$ 

i.e. 
$$DC = y - \frac{x^2}{2y}$$

#### QUESTION 6

Mathematics Extensive 1 HSC 2004

(a) 11.00 a.m. 
$$\rightarrow 5.20 \text{ p.m.} = 6\frac{1}{3} \text{ h}$$

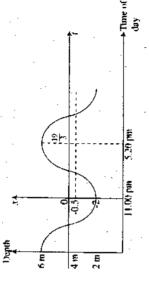

... Period 
$$T = 12\frac{2}{3} = \frac{38}{3}$$
 h

$$\therefore n = \frac{2\pi}{T} = \frac{2\pi}{\frac{3\pi}{3}} = \frac{3\pi}{19}$$

Mean tide = 4 m and 4 m and 4 m

Let x = the number of metres by which the water depth differs from 4 m at time tавет 11.00 а.т.

$$So x = -2 \cos \frac{3\pi t}{19}$$

The yacht may enter safely when  $x \ge -0.5$ 

Consider x = -0.5

$$-2\cos\frac{3\pi}{19} = -0.5$$

$$3\pi$$

$$\cos \frac{3\pi t}{19} = 0.25$$

$$\frac{3\pi t}{19} = 1.318$$
 or  $\frac{3\pi t}{19} = 2\pi - 1.318$ 

t = 10.00 h

$$= 2 h 40 min$$

.. The yacht may safely cross the lagoon between 1.40 p.m. and 9.00 p.m.

.. With no restrictions, number of arrangements = (9-1)!

$$= 40320$$

(ii) Suppose that host and hostess do sit next to each other.

Then they may be arranged in 2! ways while the guests may be arranged in 7!

 $\therefore$  Number of ways = 2! × 7!

$$= 10.080$$

.. Number of ways if host and hostess are separated

$$=40320-10080$$

$$= 30240$$

(iii) Probability = 
$$\frac{29}{32}C_{13}$$

 $= 2.23 \times 10^{-4}$ 

**QUESTION 7** 

(a) 
$$v = \sqrt{8x - x^2}$$

$$v^2 = 8x - x^2$$

$$\frac{1}{2}v^2 = 4x - \frac{x^2}{2}$$

$$\frac{1}{2}v^2 = 4x - \frac{x}{2}$$
$$a = \frac{d}{dx} \left(\frac{1}{2}v^2\right) = 4 - x$$

.. When x = 3, a = 1

(b) (i) Substituting 
$$t = \frac{x}{V \cos \alpha}$$
 into  $y = Vt \sin \alpha - \frac{1}{2}gt^2$ 

gives 
$$y = x \tan \alpha - \frac{gx^2}{2V^2 \cos^2 \alpha}$$
  
i.e.  $y = x \tan \alpha - \frac{gx^2 \sec^2 \alpha}{2V^2}$ 

(ii) 
$$y = Vt \sin \alpha - \frac{1}{2}gt^2$$

$$\dot{y} = V \sin \alpha - gt$$

The ball reaches its maximum height when y = 0.

i.e. when 
$$t = V \sin \alpha$$

Substitution into y = Vt sin  $\alpha - \frac{1}{2}gt^2$  yields

$$h = \frac{V^2 \sin^2 \alpha}{g} - \frac{1 V^2 \sin^2 \alpha}{2 g}$$

i.e. 
$$h = \frac{V^2 \sin^2 \alpha}{2g}$$

(iii) Substituting 
$$\frac{g}{V^2} = \frac{\sin^2 \alpha}{2h}$$
 into

$$y = x \tan \alpha - \frac{gx^2}{2y^2} \sec^2 \alpha$$
 yields

$$y = x \tan \alpha - \frac{x^2}{2} \cdot \frac{\sec^2 \alpha \sin^2 \alpha}{2h}$$

$$= x \tan \alpha - \frac{x^2 \sin^2 \alpha}{4h \cos^2 \alpha}$$

= 
$$x \tan \alpha - \frac{x^2 \tan^2 \alpha}{4h}$$

= 
$$x \tan \alpha (1 - \frac{x \tan \alpha}{4h})$$

(iv) 
$$1.6 = \frac{10}{\sqrt{3}} \left(1 - \frac{10}{4\sqrt{3}h}\right)$$

$$h = 1.99$$

(c) 
$$(1+x)^{2n} = {}^{2n}C_0 + {}^{2n}C_1x + {}^{2n}C_2x^2 + \dots + {}^{2n}C_nx^n + \dots + {}^{2n}C_{2n-2}x^{2n-2} + {}^{2n}C_{2n-1}x^{2n-1} + {}^{2n}C_{2n}x^{2n-1}$$

Put 
$$x=1$$
  
 $\therefore 2^{2n} = {}^{2n}C_0 + {}^{2n}C_1 + {}^{2n}C_2 + \dots {}^{2n}C_n + \dots {}^{2n}C_{2n-2} + {}^{2n}C_{2n-1} + {}^{2n}C_{2n}$ 

$$=2^{2n}C_0+2^{2n}C_1+2^{2n}C_2+\ldots+2^{2n}C_{n-1}+^{2n}C_n$$

since 
$${}^nC_r = {}^nC_{n-r}$$
  
=  $2^{2n}C_0 + 2^{2n}C_1 + 2^{2n}C_2 + ... + 2^{2n}C_{n-r} + 2^{2n}C_n - {}^{2n}C_n$ 

$$\therefore 2^{2n} + {}^{2n}C_n = 2({}^{2n}C_0 + {}^{2n}C_1 + {}^{2n}C_2 + \dots + {}^{2n}C_n)$$

$$\frac{2^{2n}}{2} + \frac{{}^{2n}C_{\mu}}{2} = {}^{2n}C_0 + {}^{2n}C_1 + {}^{2n}C_2 + \dots + {}^{2n}C_n$$

$$2^{2n-1} + \frac{(2n)!}{2n!n!} = \sum_{r=0}^{n} 2^{r}C_{r}$$

$$2^{2n-1} + \frac{(2n)!}{2(n!)^{\frac{1}{2}}} = \sum_{r=0}^{n} {}^{2n}C_r$$
